

Two photon reconstruction with **ECAL** and low mass background

Alexei Stavinskiy, Konstantin Mikhaylov

ITEP, Russia

Input

2×10^4 central UrQMD events AuAu@25AGeV (Local analysis)

Full ECAL reconstruction (version of February 2009) with

CBM root January 2009 version

(version with new geometry)

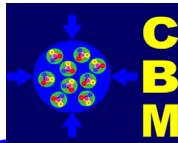

Cuts:

Minimal energy deposited in ECAL 500 MeV.

χ^2 (of photon reconstruction) < 3.

Minimal distance between cluster (DBC) > 20 cm.

Particles from target = $V_z < 1\text{cm}$ (conventional)

WA 98 experiment

[arXiv:nucl-ex/0006007]

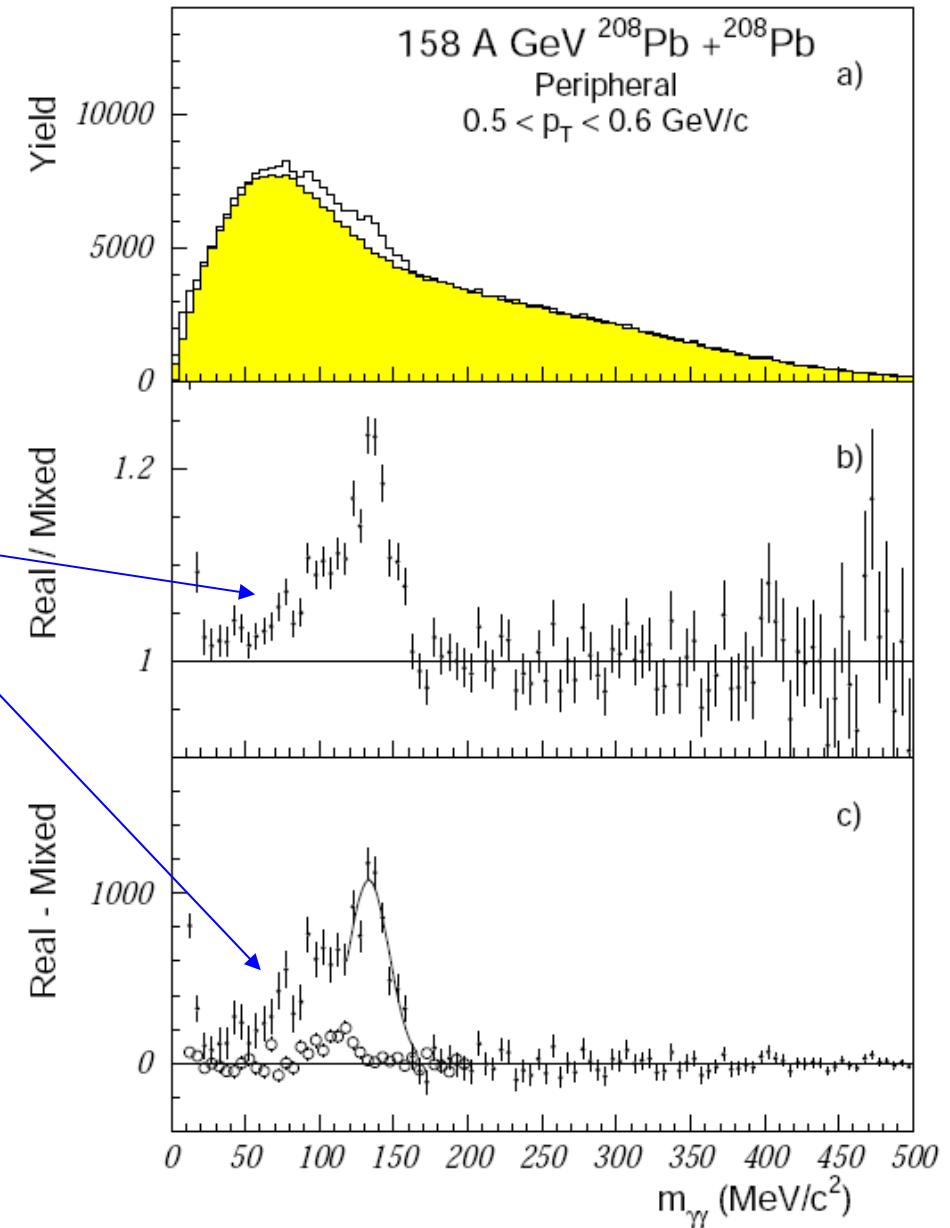

A low mass tail on the π^0 was observed.

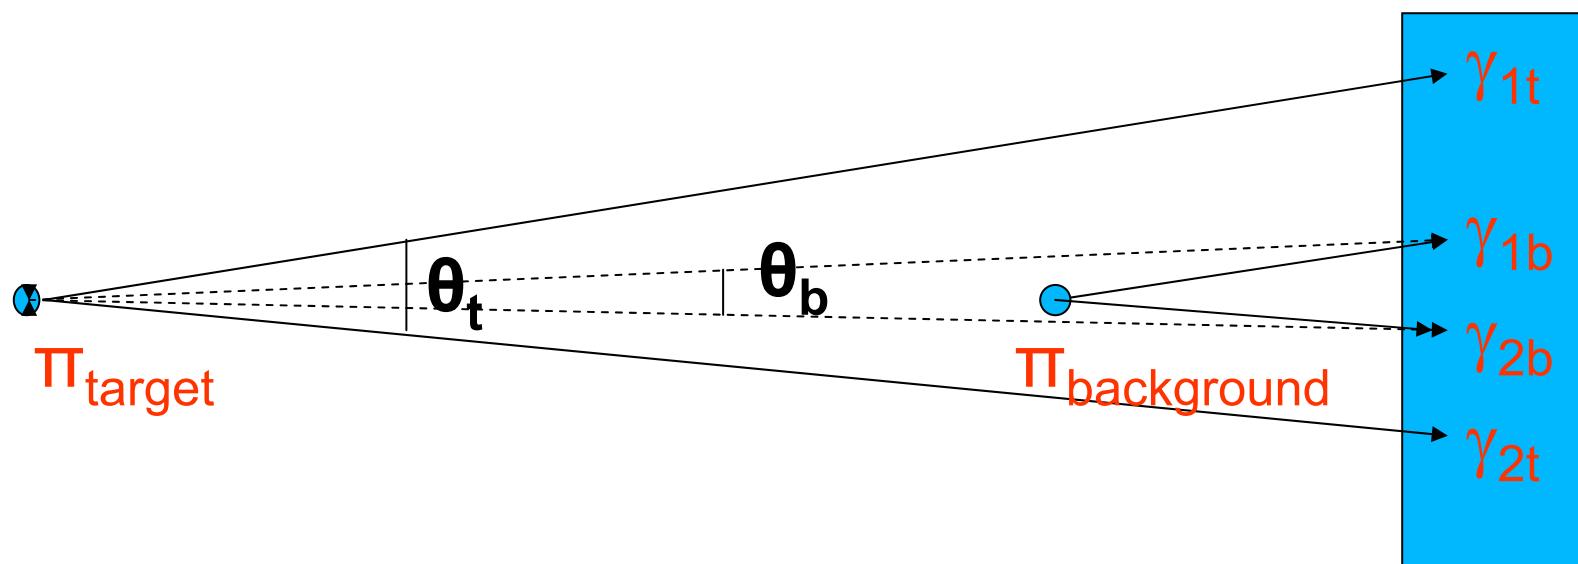

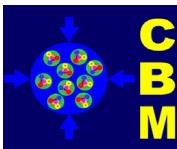

The tail can result from π^0 produced downstream from target:

- from decays (K_s^0, \dots)
- from background interaction on downstream materials

(the normalized target out background contribution is shown by the open circles

In part c))

Differences between target and background pairs:

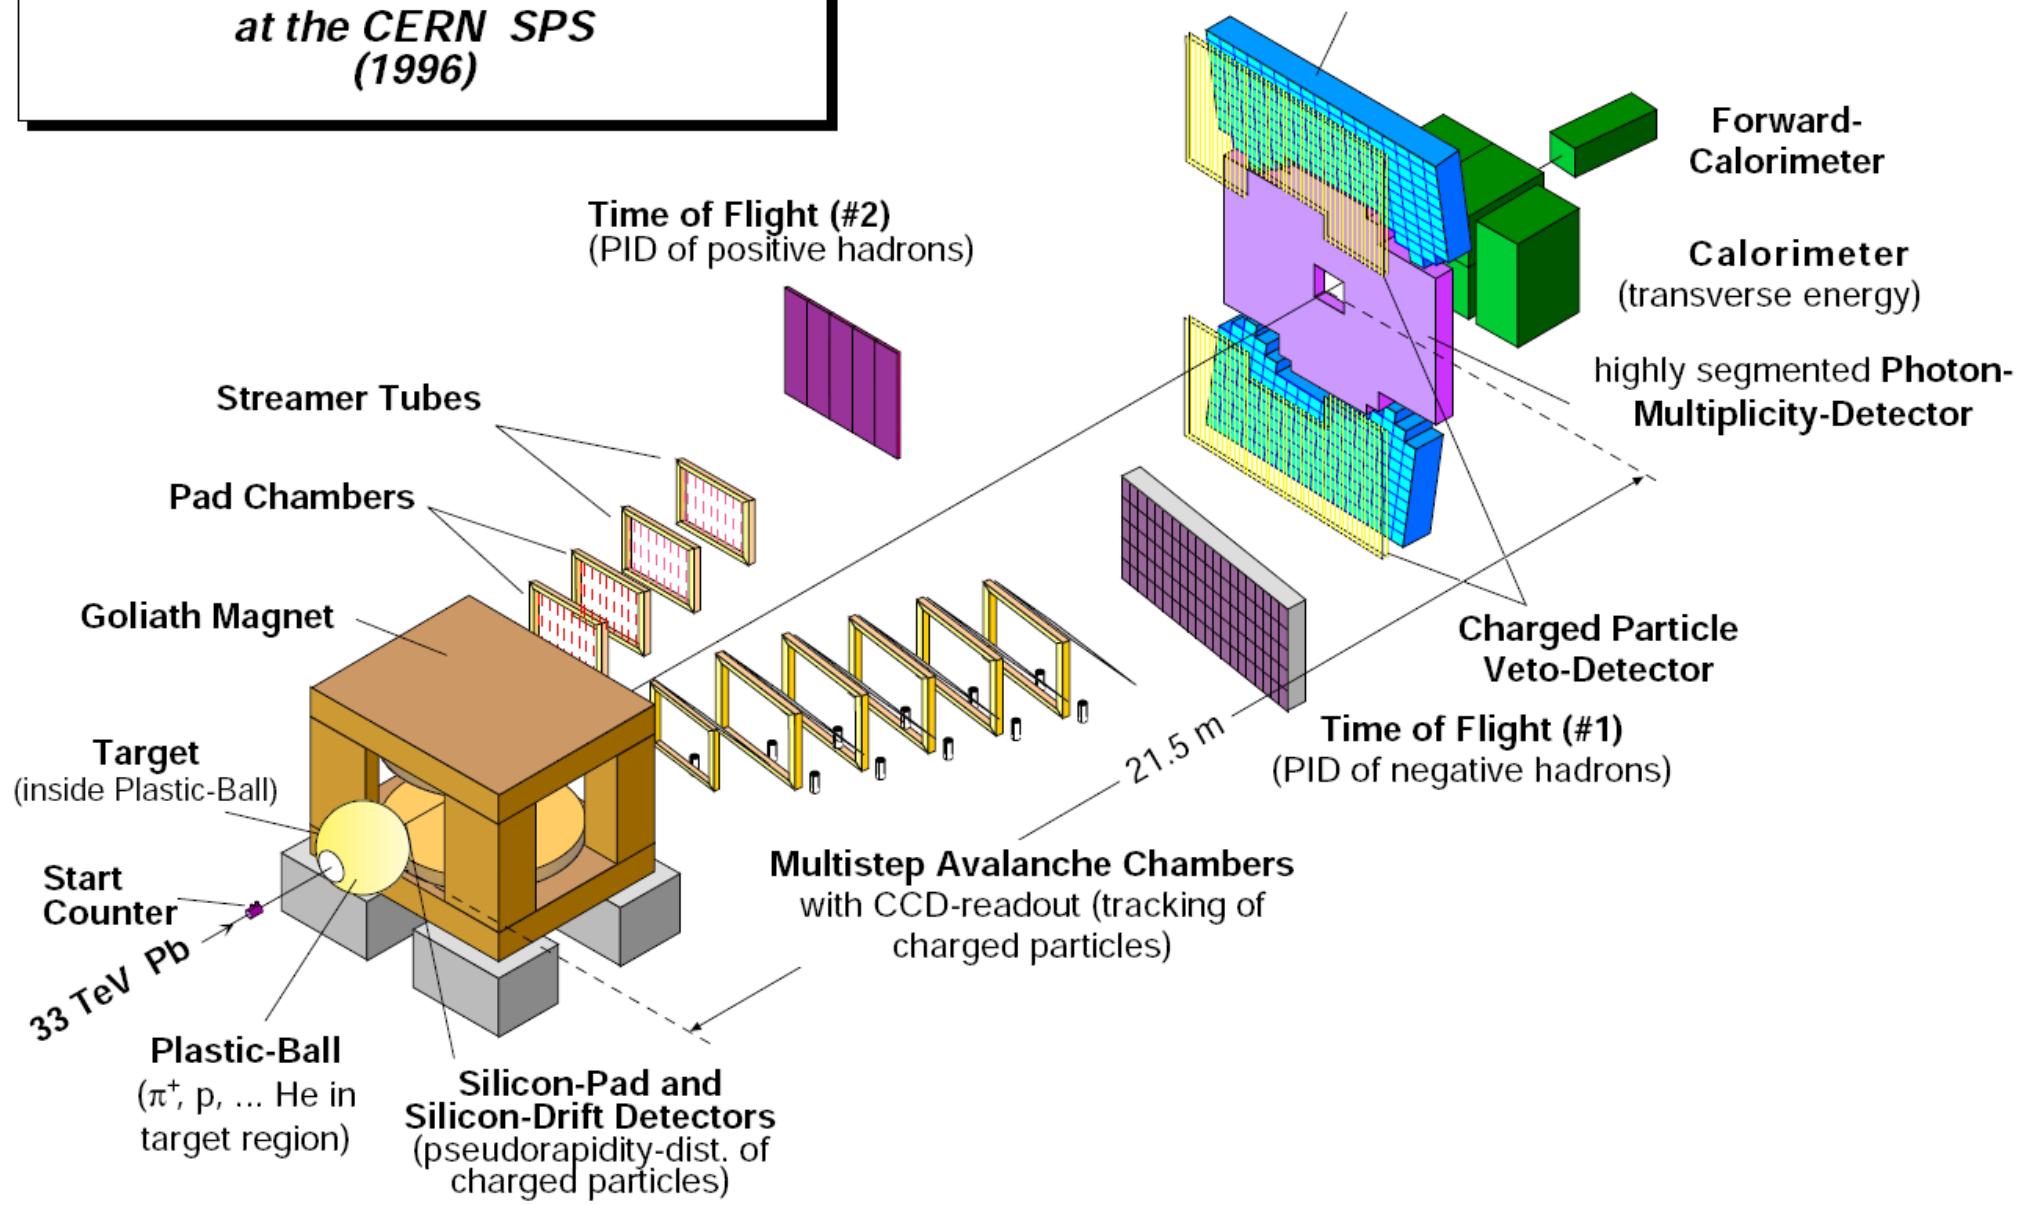

*mean photon energy higher for target photons

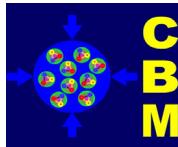

*real emission angle difference for target photons from $\pi(\eta)$ decay corresponds to measured invariant mass; this is not the case for background pairs

*vertex position is fixed for target pairs; for background pairs vertex position distribution corresponds to detectors (support) position

WWU Munster, Germany
CBM Collaboration Meeting,
Dubna 2008, October

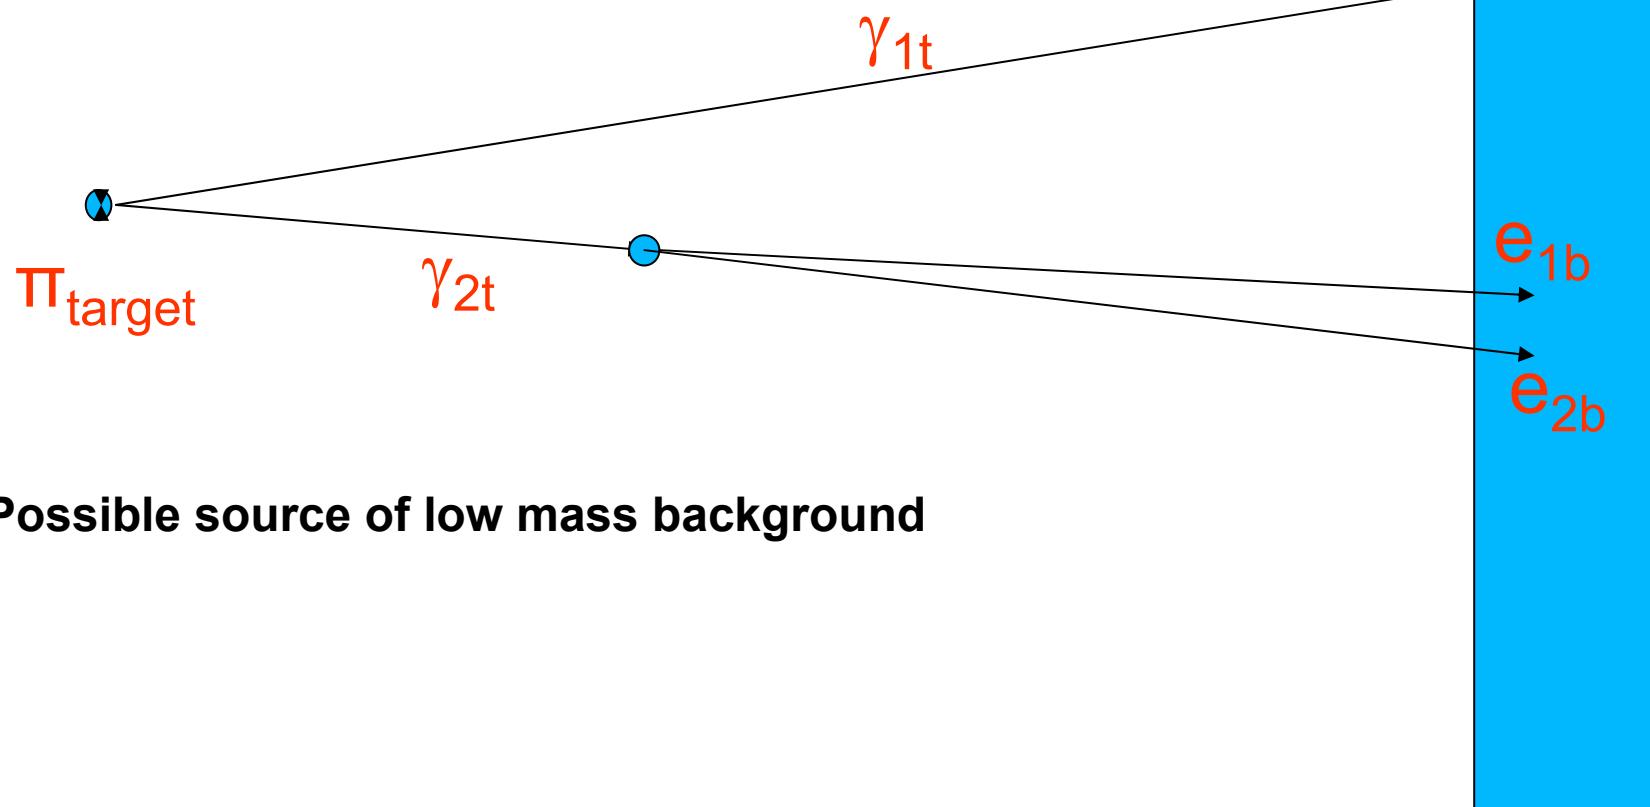

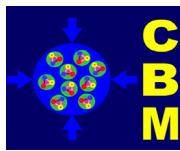

With cut on θ and m_{inv} :
conversions/ π^0 Dalitz: 9.1
conversions/all e^+e^- : 84.9%

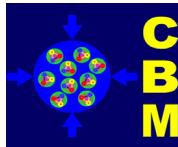

Conclusions

- The feasibility of π and η meson identification with ECAL was shown
- The low mass background in two photon invariant mass was studied
- Two main contribution to the low mass background are:
 - Interaction with downstream detector construction
 - Decay of long lived particles
- Possible cuts to reduce (slightly) low mass background:
 - Cut on gamma energy
 - Cut on distance between center of clusters
- Other possible ways:
 - Background simulations
 - Combined photon pair identification with different detectors
